## Preparation of preparing substituted indanones

The present invention relates to a simple and economically  
5 interesting process for preparing substituted indanones.

Substituted indanones are important intermediates for preparing active compounds in the fields of pharmacy and crop protection (cf. S.J. deSolms et al., J. Med. Chem., 1978, 21, 437) and for  
10 preparing metallocene complexes (cf. Chemie in unserer Zeit, 1994, 28, 204, 205). In particular, substituted indanones can be used to prepare bridged chiral metallocenes which are of great importance as highly active catalysts in olefin polymerization (cf. EP-A 129 368). The catalyst properties can be influenced in  
15 a targeted manner by variation of the ligand system, eg. by substitution. This makes it possible to achieve the desired degree of change in the polymer yield, the tacticity or the melting point of the polymers (New J. Chem., 1990, 14, 499; Organomet., 1990, 9, 3098; Angew. Chem., 1990, 102, 339;  
20 EP-A 316 155; EP-A 351 392). Bridged zirconocenes containing, as  $\pi$  ligands, substituted indenyl radicals which bear the bridge in position 1, preferably a hydrocarbon radical in position 2 and a hydrocarbon radical, preferably an aryl radical, in position 4 have been found to be particularly active and stereoselective  
25 catalyst systems (EP 0 576 970 A1; EP 0 629 632 A2). The ligand systems used for these highly active metallocenes are prepared from the corresponding indenenes which are in turn obtained from indanones which are substituted in the appropriate positions (EP 0 576 970 A1; EP 0 629 632 A2). These indanones are  
30 synthesized from commercially available precursors or precursors known in the literature, for example as follows:

EP 0 576 970 A1:

The 2-methyl-4-phenylindanone is converted into the corresponding  
45 indene, for example by reduction of the ketone function to the alcohol and subsequent dehydration.

EP 0 629 632 A2:

35 The three synthetic routes shown by way of example go through 2-,  
4-substituted indanones which have in each case been obtained by  
Friedel-Crafts cyclization of the corresponding 3-arylpropionic  
acids. The syntheses are multistage processes in which relatively  
40 expensive starting compounds are used. Furthermore, in the  
syntheses disclosed in EP 0 629 632, the introduction of a  
protective group cannot be avoided. The processes shown are thus  
very costly routes.

## 3

It is therefore an object of the present invention to find a simple, flexible, inexpensive process for preparing substituted indanones which are important intermediates for preparing active compounds and metallocene complexes.

5

We have now surprisingly found that substituted indanones which contain a leaving group can be used to prepare, in a simple manner, other indanones which can be used, inter alia, for preparing active compounds and metallocene complexes.

10

The present invention accordingly provides a process for the preparation of indanones of the formula II from indanones of the formula I or of indanones of the formula IIa from indanones of the formula Ia

In the process of the present invention, the indanones of the

25 formula I or Ia are converted directly into the indanones of the formula II or IIa in one reaction step by reaction with the coupling component. In this reaction, no use is made of protective groups for the carbonyl function of the indanone of the formula I or Ia.

30 For the purposes of this application, the term "heteroatom" refers to any atom of the Periodic Table of the Elements with the exception of carbon and hydrogen. A heteroatom is preferably an atom of Group 14, 15 or 16 of the Periodic Table of the Elements

35 with the exception of carbon. The term "heterocyclic group" refers to a heteroatom-containing cyclic group.

In the process of the present invention, particular preference is given to using indanones of the formula I or Ia in which

40  $\text{X}$  is chlorine, bromine, iodine, triflate, nonaflate, mesylate, ethylsulfonate, benzenesulfonate, tosylate, triisopropylbenzenesulfonate, formate, acetate, trifluoroacetate, nitrobenzoate, halogenated arylcarboxylates, in particular fluorinated benzoate, methyl carbonate, ethyl carbonate, benzyl carbonate, tert-butyl

In the process of the present invention, at least one indanone of the formula I or Ia is reacted with at least one coupling component, forming the indanones of the formulae II and IIa. In  
 20 this reaction, the coupling component serves to introduce the radical  $R^3$ . It is also possible for the coupling component to convert one or more of the radicals  $Y^1$ ,  $Y^2$  and  $Y^3$  which are as defined for X into radicals  $Y^4$ ,  $Y^5$  and  $Y^6$  which are as defined for  $R^3$ .

- 25 The coupling components are preferably compounds containing elements of Groups 13-17 of the Periodic Table of the Elements. The coupling components are preferably compounds containing boron, carbon, silicon, germanium, tin, phosphorus or fluorine.
- 30 The coupling components are particularly preferably compounds containing boron, carbon, silicon, tin or phosphorus.

Preferred boron-containing coupling components are boronic acids and boronic esters, for example of the type

The indanones of the formula I or Ia can be prepared by methods similar to those known from the literature (eg. US 5,489,712; 15 US 4,070,539; S.J. deSolms et al., J. Med. Chem., 1978, 21, 437). To prepare indanones of the formula I, for example, an aryl alkyl ketone of the formula (A) can be methylenated and subsequently subjected to a Nazarov cyclization.

- 30 R<sup>1</sup>, X, Y<sup>1</sup>, Y<sup>2</sup> and Y<sup>3</sup> in the formulae A, B and I are as defined above for formula I.

In the case of an aryl alkyl ketone, the methylene group can, for example, be introduced by an aldol condensation with formaldehyde 35 as methylene source or by a Mannich reaction, in which, for example, N,N,N',N'-tetramethyldiaminomethane, Eschenmoser's salt or urotropien/acetic anhydride can be used as methylene source. It is indicated in the literature (US 5,489,712) that the aldol condensation of formaldehyde, which is the most inexpensive 40 methylene source, and aryl alkyl ketones proceeds in poor yields and the management of the reaction is said to be complicated. M.M. Curzu et al. in Synthesis (1984) 339 state that in the aldol condensation of formaldehyde and certain aryl alkyl ketones, considerable amounts of starting material remain unreacted and 45 undesirable by-products such as the primary aldol product containing a hydroxymethyl group are present in the end product.

## 48

It has surprisingly been found that the aldol condensation (ie. the introduction of the methylene group) of aryl alkyl ketones proceeds virtually quantitatively under basic conditions using formaldehyde, and the primary aldol product containing a

- 5 hydroxymethyl group cannot be observed spectroscopically. Here, preferred aryl alkyl ketones of the formula A are those in which X is a halogen.

- The aldol condensation is carried out using a formaldehyde source, preferably aqueous formalin solution, and a base, preferably an alkali metal carbonate or alkaline earth metal carbonate or an alkali metal hydroxide or alkaline earth metal hydroxide, particularly preferably an aqueous sodium hydroxide solution, at 0-100°C, preferably 20-60°C.

- The molar ratio of base to aryl alkyl ketone is in the range from 15 0.01 to 5, preferably in the range from 0.1 to 2.

The molar ratio of formaldehyde to aryl alkyl ketone is in the range from 0.5 to 1.5, preferably in the range from 0.9 to 1.2.

- The concentration of the aryl alkyl ketone in the reaction mixture (total volume) is in the range from 0.01 to 6 mol/l, preferably from 0.1 to 2 mol/l. The aryl alkyl ketone can be 20 diluted with inert solvents such as ethers, hydrocarbons or halogenated hydrocarbons. The reaction can be carried out in a single-phase or multiphase system.

- In the case of multiphase reaction mixtures, phase transfer 25 catalysts can be added to accelerate the reaction.

The reaction time is usually from 15 minutes to 12 hours or longer.

- The reaction can also be carried out in an inert gas atmosphere and the pressure in the reaction vessel can be either below or 30 above atmospheric pressure.

The subsequent cyclization to form the indanone is carried out by literature methods (J.H. Burckhalter, R.C. Fuson, J. Amer. Chem. Soc., 1948, 70, 4184; E.D. Thorsett, F.R. Stermitz, Synth.

- 35 Commun., 1972, 2, 375; Synth. Commun., A. Bhattacharya, B. Segmuller, A. Ybarra, 1996, 26, 1775; U.S. Pat.

- No. 5,489,712). The cyclization is preferably carried out under acid conditions. As cyclization reagent, it is possible to use acids such as protic acids (eg. sulfuric acid, polyphosphoric acid, methanesulfonic acid) or Lewis acids (eg. aluminum trichloride, boron trifluoride). The reaction product from the aldol condensation can be diluted with an inert solvent before addition to the cyclization reagent, or can be added in undiluted form.

To prepare indanones of the formula I and Ia in which X is an oxygen-containing leaving group, for example a triflate group, the starting materials used are preferably hydroxyindanones, some of which are known from the literature (eg. Bringmann et al., 5 Liebigs Ann. Chem., 1985, 2116-2125), and the hydroxy group is converted by literature methods into an oxygen-containing leaving group X, eg. triflate (eg.: P.J. Stang, Synthesis, 1982, 85; V. Percec, J. Org. Chem., 1995, 60, 176; Autorenkollektiv, Organikum, VEB Deutscher Verlag der Wissenschaften, 1976).

10

Some of the aryl alkyl ketones are known from the literature or they can easily be prepared by literature methods (eg.: R.C. Larock, Comprehensive Organic Transformations, VCH, 1989).

15 The invention further provides substituted indanones of the formula IV

Both indanones of the formulae I and Ia and also indanones of the  
 5 formulae II and IIa are suitable, inter alia, as intermediates in  
 the preparation of metallocenes and active compounds in the  
 fields of pharmacy and crop protection.

The indanones of the formulae II and IIa can easily be converted  
 10 into the indenenes of the formulae V and Va by literature methods  
 (eg.: R.C. Larock, Comprehensive Organic Transformations, VCH,  
 1989, EP 0 629 632 A2).

20

25

30

In the formulae II, IIa, V and Va, the radicals R¹, R³, Y⁴, Y⁵ and  
 35 Y⁶ are as defined above for formulae II and IIa.

Metallocenes can be prepared from the indenenes of the formulae V  
 and Va by literature methods (eg. EP 576 970, EP 629 632).

Preference is given to unbridged or bridged metallocenes of the  
 40 formula (VI)

$R^9$  and  $R^{10}$  are identical or different and are each a hydrogen atom, hydroxy or a halogen atom or a  $C_1$ - $C_{40}$ -group such as  $C_1$ - $C_{10}$ -alkyl,  $C_1$ - $C_{10}$ -alkoxy,  $C_6$ - $C_{10}$ -aryl,  $C_6$ - $C_{10}$ -aryloxy,  $C_2$ - $C_{10}$ -alkenyl,  $C_7$ - $C_{40}$ -arylalkyl,  $C_7$ - $C_{40}$ -alkylaryl,  $C_8$ - $C_{40}$ -arylalkenyl, preferably hydrogen,  $C_1$ - $C_3$ -alkyl, in particular methyl,  $C_1$ - $C_3$ -alkoxy,  $C_6$ -aryl,  $C_6$ -aryloxy,  $C_2$ - $C_{10}$ -alkenyl,  $C_7$ - $C_{10}$ -arylalkyl,  $C_7$ - $C_{10}$ -alkylaryl,  $C_8$ - $C_{10}$ -arylalkenyl or a halogen atom, in particular chlorine,  $x$  is zero or 1,

$R^{11}$  is a bridge such as

35

where  $M^2$  is carbon, silicon, germanium or tin, preferably silicon or carbon, in particular silicon,

$p$  is 1, 2 or 3, preferably 1 or 2, in particular 1,

another (eg. when one Y<sup>6</sup> = H, and the other Y<sup>6</sup> = CH<sub>3</sub> or when one  
Y<sup>6</sup> = CH<sub>3</sub> and the other Y<sup>6</sup> = C<sub>2</sub>H<sub>5</sub>).

Further examples are the titanocenes and hafnocenes corresponding  
to the zirconocenes listed above.

The metallocenes which can be prepared from indanones via indenenes  
35 are highly active catalyst components for olefin polymerization.  
Depending on the substitution pattern of the ligands, the  
metallocenes can be formed as a mixture of isomers. For the  
polymerization, the metallocenes are preferably used in  
isomerically pure form. The use of the racemate is sufficient in  
40 most cases.

However, it is also possible to use the pure enantiomer in the  
(+) or (-) form. An optically active polymer can be prepared  
using the pure enantiomers. However, the configurational isomers  
45 of the metallocenes should be separated off, since the  
polymerization-active center (the metal atom) in these compounds  
usually produces a polymer having different properties. For

certain applications, for example flexible moldings, this can be quite desirable.

The present invention therefore also provides a process for  
5 preparing a polyolefin by polymerization of at least one olefin in the presence of a catalyst comprising at least one cocatalyst and at least one stereorigid metallocene compound of the formula I. For the purposes of the present invention, the term polymerization encompasses both homopolymerization and copolymerization.

10

In the process of the present invention, preference is given to polymerizing one or more olefins of the formula  $R^a-CH=CH-R^b$ , where  $R^a$  and  $R^b$  are identical or different and are each a hydrogen atom or a hydrocarbon radical having from 1 to 20 carbon atoms, in  
15 particular from 1 to 10 carbon atoms, and  $R^a$  and  $R^b$  together with the atoms connecting them may form one or more rings. Examples of such olefins are 1-olefins having from 2 to 40 carbon atoms, preferably 2-10 carbon atoms, for example ethylene, propylene, 1-butene, 1-pentene, 1-hexene, 4-methyl-1-pentene or 1-octene,  
20 styrene, dienes such as 1,3-butadiene, isoprene, 1,4-hexadiene or cyclic olefins such as norbornene or ethylidenenorbornene.

In the process of the present invention, preference is given to homopolymerizing ethylene or propylene or copolymerizing ethylene with one or more cyclic olefins such as norbornene and/or one or  
25 more acyclic 1-olefins having from 3 to 20 carbon atoms, eg. propylene, and/or one or more dienes having from 4 to 20 carbon atoms, eg. 1,3-butadiene or 1,4-hexadiene. Examples of such copolymers are ethylene-norbornene copolymers, ethylene-propylene copolymers and ethylene-propylene-1,4-hexadiene copolymers.

30

The polymerization is preferably carried out at from -60 to 250°C, particularly preferably from 50 to 200°C. The pressure is preferably from 0.5 to 2000 bar, particularly preferably from 5 to 64 bar.

35

The polymerization can be carried out in solution, in bulk, in suspension or in the gas phase, continuously or batchwise, in one or more stages. Preferred embodiments are gas-phase and solution polymerization.

40

The catalyst used in the process of the present invention preferably comprises one metallocene compound. It is also possible to use mixtures of two or more metallocene compounds, eg. for preparing polyolefins having a broad or multimodal molar  
45 mass distribution.

In principle, suitable cocatalysts for the process of the present invention are all compounds which, owing to their Lewis acidity, can convert the neutral metallocene into a cation and stabilize the latter ("labile coordination"). Furthermore, the catalyst or the anion formed therefrom should undergo no further reactions with the metallocene cation formed (EP 427 697). The cocatalyst used is preferably an aluminum compound and/or a boron compound.

- The boron compound preferably has the formula  $R^a_xNH_4-xBR^b_4$ ,  $R^a_xPH_4-xBR^b_4$ ,  $R^a_3CBR^b_4$  or  $BR^b_3$ , where x is from 1 to 4, preferably 3, the radicals  $R^a$  are identical or different, preferably identical, and are  $C_1$ - $C_{10}$ -alkyl or  $C_6$ - $C_{18}$ -aryl or two radicals  $R^a$  together with the atoms connecting them form a ring, and the radicals  $R^b$  are identical or different, preferably identical, and are  $C_6$ - $C_{18}$ -aryl which may be substituted by alkyl, haloalkyl or fluorine. In particular,  $R^a$  is ethyl, propyl, butyl or phenyl and  $R^b$  is phenyl, pentafluorophenyl, 3,5-bis(trifluoromethyl)phenyl, mesityl, xylyl or tolyl (EP 277 003, EP 277 004 and EP 426 638).
- 20 As cocatalyst, preference is given to using an aluminum compound such as aluminoxane and/or an aluminum alkyl.

The cocatalyst used is particularly preferably an aluminoxane, in particular of the formula C for the linear type and/or the formula D for the cyclic type,

40 where, in the formulae C and D, the radicals  $RC$  are identical or different and are each hydrogen or a  $C_1$ - $C_{20}$ -hydrocarbon group such as a  $C_1$ - $C_{18}$ -alkyl group, a  $C_6$ - $C_{18}$ -aryl group or benzyl, and p is an integer from 2 to 50, preferably from 10 to 35.

Preferably, the radicals  $R^C$  are identical and are hydrogen, methyl, isobutyl, phenyl or benzyl, particularly preferably methyl.

- 5 If the radicals  $R^C$  are different, they are preferably methyl and hydrogen or alternatively methyl and isobutyl, with hydrogen or isobutyl preferably being present in a numerical proportion of from 0.01 to 40% (of the radicals  $R^C$ ).
- 10 The methods of preparing the aluminoxanes are known. The precise spatial structure of the aluminoxanes is not known (J. Am. Chem. Soc. (1993) 115, 4971). For example, it is conceivable that chains and rings are joined to form larger two-dimensional or three-dimensional structures.
- 15 Regardless of the method of preparation, all aluminoxane solutions have in common a variable content of unreacted aluminum starting compound which is present in free form or as adduct.
- 20 It is possible to preactivate the metallocene compound with a cocatalyst, in particular an aluminoxane, before use in the polymerization reaction. This significantly increases the polymerization activity. The preactivation of the metallocene compound is preferably carried out in solution. Here, the
- 25 metallocene compound is preferably dissolved in a solution of the aluminoxane in an inert hydrocarbon. Suitable inert hydrocarbons are aliphatic or aromatic hydrocarbons. Preference is given to using toluene.
- 30 The concentration of the aluminoxane in the solution is in the range from about 1% by weight to the saturation limit, preferably from 5 to 30% by weight, in each case based on the total amount of solution. The metallocene can be used in the same concentration but it is preferably used in an amount of from  $10^{-4}$
- 35 to 1 mol per mol of aluminoxane. The preactivation time is from 5 minutes to 60 hours, preferably from 5 to 60 minutes. The preactivation is carried out at from  $-78$  to  $100^\circ\text{C}$ , preferably from  $0$  to  $80^\circ\text{C}$ .
- 40 The metallocene compound is preferably employed in a concentration, based on the transition metal, of from  $10^{-3}$  to  $10^{-8}$  mol, preferably from  $10^{-4}$  to  $10^{-7}$  mol, of transition metal per  $\text{dm}^3$  of solvent or per  $\text{dm}^3$  of reactor volume. The aluminoxane is preferably used in a concentration of from  $10^{-6}$  to  $10^{-1}$  mol,
- 45 preferably from  $10^{-5}$  to  $10^{-2}$  mol, per  $\text{dm}^3$  of solvent or per  $\text{dm}^3$  of reactor volume. The other cocatalysts mentioned are used in

approximately equimolar amounts to the metallocene compound. However, higher concentrations are also possible in principle.

The aluminoxane can be prepared in various ways by known methods.  
5 One of the methods is, for example, reacting an aluminum-hydrocarbon compound and/or a hydridoaluminum-hydrocarbon compound with water (gaseous, solid, liquid or bound - for example as water of crystallization) in an inert solvent (for example toluene). To prepare an aluminoxane having different  
10 radicals  $R^C$ , for example, two different aluminum trialkyls corresponding to the desired composition are reacted with water.

To remove catalyst poisons present in the olefin, a purification step using an aluminum compound, preferably an aluminum alkyl  
15 such as trimethylaluminum or triethylaluminum, is advantageous. This purification can be carried out either in the polymerization system itself or the olefin is brought into contact with the aluminum compound and subsequently separated off again before addition to the polymerization system.

20 As molar mass regulator and/or to increase the catalyst activity, hydrogen can be added in the process of the present invention. This makes it possible to obtain low molecular weight polyolefins such as waxes.

25 In the process of the present invention, the metallocene compound is preferably reacted with the cocatalyst outside the polymerization reactor in a separate step using a suitable solvent. In this step, the catalyst can be applied to a support.

30 In the process of the present invention, a prepolymerization can be carried out by means of the metallocene compound. The prepolymerization is preferably carried out using the (or one of the) olefin(s) used in the polymerization.

35 The catalyst used in the process of the present invention can be supported. The application to a support enables, for example, the particle morphology of the polyolefin prepared to be controlled. Here, the metallocene compound can be reacted first with the  
40 support and subsequently with the cocatalyst. The cocatalyst can also be supported first and subsequently reacted with the metallocene compound. It is also possible to apply the reaction product of metallocene compound and cocatalyst to a support. Suitable support materials are, for example, silica gels,  
45 aluminum oxides, solid aluminoxane or other inorganic support materials such as magnesium chloride. Another suitable support material is a polyolefin powder in finely divided form. The

supported cocatalyst can be prepared, for example, as described in EP 567 952.

Preferably, the cocatalyst, eg. aluminoxane, is applied to a support such as silica gels, aluminum oxides, solid aluminoxane, other inorganic support materials or else a polyolefin powder in finely divided form and then reacted with the metallocene.

As inorganic supports, it is possible to use oxides which have been produced flame-pyrolytically by combustion of element halides in a hydrogen/oxygen flame or can be prepared as silica gels having particular particle size distributions and particle shapes.

The preparation of the supported cocatalyst can be carried out, for example, as described in EP 578 838 in the following manner in a stainless steel reactor having an explosion-proof design with a pumped circulation system and a pressure rating of 60 bar, with inert gas supply, temperature control by means of jacket cooling and a second cooling circuit via a heat exchanger on the pumped circulation system. The pumped circulation system draws in the reactor contents via a connection in the bottom of the reactor by means of a pump and pushes it into a mixer and through a riser line via a heat exchanger back into the reactor. The mixer is configured such that in the inlet there is located a constricted tube cross section where the flow velocity is increased and into the turbulence zone of which there is introduced, axially and opposite to the flow direction, a thin feed line through which, pulsed, a defined amount of water under 40 bar of argon can be fed in. The reaction is monitored by means of a sampler on the pumped circulation system.

However, other reactors are also suitable in principle.

The above-described reactor having a volume of 16 dm<sup>3</sup> is charged with 5 dm<sup>3</sup> of decane under inert conditions. 0.5 dm<sup>3</sup> (= 5.2 mol) of trimethylaluminum are added at 25°C. 250 g of silica gel SD 3216-30 (Grace AG), which have been dried beforehand at 120°C in an argon-fluidized bed, are then introduced into the reactor through a solids funnel and are homogeneously distributed by means of the stirrer and the pumped circulation system. A total amount of 76.5 g of water is added to the reactor in portions of 0.1 cm<sup>3</sup> every 15 seconds over a period of 3.25 hours. The pressure, caused by the argon and the gases evolved, is kept constant at 10 bar by means of a pressure regulation valve. After all the water has been introduced, the pumped circulation system

is switched off and stirring is continued for another 5 hours at 25°C.

The supported cocatalyst prepared in this way is used as a 10% strength suspension in n-decane. The aluminum content is 1.06 mmol of Al per cm<sup>3</sup> of suspension. The isolated solid contains 31% by weight of aluminum and the suspension medium contains 0.1% by weight of aluminum.

10 Further possible ways of preparing a supported cocatalyst are described in EP 578 838.

The metallocene of the present invention is then applied to the supported cocatalyst by stirring the dissolved metallocene with 15 the supported cocatalyst. The solvent is removed and replaced by a hydrocarbon in which both cocatalyst and the metallocene are insoluble.

The reaction to form the supported catalyst system is carried out 20 at from -20 to +120°C, preferably from 0 to 100°C, particularly preferably from 15 to 40°C. The metallocene is reacted with the supported cocatalyst by combining the cocatalyst as a suspension having a concentration of from 1 to 40% by weight, preferably from 5 to 20% by weight, in an aliphatic, inert suspension medium 25 such as n-decane, hexane, heptane or diesel oil with a solution of the metallocene in an inert solvent such as toluene, hexane, heptane or dichloromethane or with the finely milled solid metallocene. Conversely, a solution of the metallocene can also be reacted with the solid cocatalyst.

30 The reaction is carried out by intensive mixing, for example by stirring, at a molar Al/M<sup>1</sup> ratio of from 100/1 to 10,000/1, preferably from 100/1 to 3000/1, and a reaction time of from 5 to 120 minutes, preferably from 10 to 60 minutes, particularly 35 preferably from 10 to 30 minutes, under inert conditions. During the reaction time for preparing the supported catalyst system, particularly when using the metallocenes of the present invention having absorption maxima in the visible region, changes occur in the color of the reaction mixture and these enable the progress 40 of the reaction to be followed.

After the reaction time has expired, the supernatant solution is separated off, for example by filtration or decantation. The remaining solid is washed from 1 to 5 times with an inert 45 suspension medium such as toluene, n-decane, hexane, diesel oil or dichloromethane to remove soluble constituents in the catalyst

formed, in particular to remove unreacted and therefore soluble metallocene.

The supported catalyst system prepared in this way can be  
5 resuspended as vacuum-dried powder or while still moist with solvent and metered into the polymerization system as a suspension in one of the abovementioned inert suspension media.

If the polymerization is carried out as a suspension or solution  
10 polymerization, an inert solvent customary for the Ziegler low-pressure process is used. For example, the polymerization is carried out in an aliphatic or cycloaliphatic hydrocarbon, for example propane, butane, hexane, heptane, isooctane, cyclohexane or methylcyclohexane. It is also possible to use a petroleum or  
15 hydrogenated diesel oil fraction. Toluene can also be used. Preference is given to carrying out the polymerization in the liquid monomer.

Before addition of the catalyst, in particular the supported  
20 catalyst system (comprising the metallocene of the present invention and a supported cocatalyst), it is possible to introduce, in addition, another aluminum alkyl compound such as trimethylaluminum, triethylaluminum, triisobutylaluminum, trioctylaluminum or isoprenylaluminum into the reactor to make  
25 the polymerization system inert (for example to remove catalyst poisons present in the olefin). This is added to the polymerization system in a concentration of from 100 to 0.01 mmol of Al per kg of reactor contents. Preference is given to triisobutylaluminum and triethylaluminum in a concentration of  
30 from 10 to 0.1 mmol of Al per kg of reactor contents. This makes it possible to select a small molar Al/M<sup>1</sup> ratio in the synthesis of a supported catalyst system. If inert solvents are used, the monomers are metered in in gaseous or liquid form.

## 25 1. 7-Chloro-2-methyl-1-indanone (1)

50 g (0.3 mol) of 2-chloropropiophenone (B.L. Jenson et al., Tetrahedron, 1978, 1627) together with 24.55 ml (0.33) of 37% strength formaldehyde solution were placed in the reaction  
 30 vessel. A solution of 12 g of sodium hydroxide in 600 ml of water was added thereto. The mixture was stirred for 2.5 hours at 40°C. The phases were separated, the aqueous phase was extracted 3 times with 50 ml each time of methylene chloride, the combined organic phases were washed with 100 ml of 1N HCl solution and  
 35 dried over magnesium sulfate. The methylene chloride solution was added while stirring to 400 g of hot (65°C) concentrated sulfuric acid over a period of 2.25 hours. The methylene chloride distilled off during this procedure. After the addition was complete, stirring was continued for another 0.5 hour at 65°C. At  
 40 room temperature, the cool sulfuric acid solution was slowly added to an ice-cold mixture of 325 ml of methylene chloride and 325 ml of water. The phases were separated, the sulfuric acid solution was extracted twice with 250 ml each time of methylene chloride, the combined organic phases were washed with 200 ml of  
 45 saturated sodium hydrogencarbonate solution, 200 ml of water and 200 ml of saturated sodium chloride solution and dried over magnesium sulfate. After removal of the solvent, the brown liquid

58. Dimethylsilanediylbis(2-methyl-4-(1-naphthyl)indenyl)-  
zirconium dichloride (58)

14.4 ml (50 mmol) of a 20% strength solution of butyllithium in  
5 toluene were added at room temperature to a solution of 10 g  
(38 mmol) of (37) in 100 ml of toluene and 5 ml of THF and the  
mixture was heated at 80°C for 2 hours. The suspension was  
subsequently cooled to 0°C and admixed with 2.5 g (19 mmol) of  
dimethyldichlorosilane. The reaction mixture was heated at 80°C  
10 for another 1 hour and subsequently washed with 50 ml of water.  
The solvent was removed under reduced pressure and the residue  
was recrystallized from heptane at -20°C. 8.2 g of ligand were  
obtained as colorless crystals. 8.0 g (14 mmol) of the ligand  
were dissolved in 70 ml of diethyl ether, admixed at room  
15 temperature with 10.5 ml of a 20% strenght solution of butyl-  
lithium in toluene and subsequently refluxed for 3 hours. The  
solvent was removed under reduced pressure and the residue  
together with 50 ml of hexane was filtered on a G3 Schlenk frit,  
washed with 50 ml of hexane and dried (0.1 mbar, 20°C). The  
20 dilithium salt was added at -78°C to a suspension of 3.2 g  
(14 mmol) of zirconium tetrachloride in 80 ml of methylene  
chloride and, while stirring, warmed to room temperature over a  
period of 18 hours. The mixture was filtered on a G3 frit and the  
residue was extracted with a total of 400 ml of methylene  
25 chloride added a little at a time. The combined filtrates were  
very largely freed of solvent under reduced pressure. The  
crystals which precipitated from methylene chloride were  
isolated. This gave 1.5 g of (58) having a racemate:meso ratio of  
1:1. Recrystallization from methylene chloride gave the racemic  
30 complex in the form of yellow crystals.
